

Codex Response Transcript

Project: darts-pats.netlify.app

GitHub repository: <https://github.com/heggkj/darts-pats>

Generated: May 8, 2026, America/New_York

Scope: Assistant responses and working updates from this Codex session through the PDF-generation request. Tool output and user messages are omitted.

1. Working update

I'll get the local shape of the workspace first: where the starter kit landed, whether the target repo is already cloned here, and what Git state we're starting from.

2. Working update

The workspace has the starter zip but isn't itself a Git repo, so I'm going to inspect the archive, then clone heggkj/darts-pats beside it and copy the kit in there.

3. Working update

The archive contains exactly the darts-pats-exhibit/ folder and the files you called out. Next I'm extracting it and cloning the GitHub repo so the copy happens into a real main checkout.

4. Working update

The repo cloned cleanly and is empty, which makes this a straightforward initial population. I'm copying the starter folder contents into the repo root now, including hidden files like .gitignore and .github.

5. Working update

The files are in place. I'm doing a quick preservation check on the named assets, then I'll install dependencies and let the Astro build tell us what still needs attention.

6. Working update

The named files are present in the target repo. Starting dependency install now; after that I'll run the production build and patch anything the compiler trips over.

7. Working update

Install finished cleanly with no reported vulnerabilities. I'm running the Astro build next; this is the real compatibility check.

8. Working update

The build passed on the first run, so there's no compiler fix-up needed. I'm checking the final diff shape now, then I'll commit with your exact message and push main.

9. Working update

The commit set is clean: starter files plus the generated package-lock.json, with build outputs and node_modules ignored. I'm committing that initial snapshot now.

10. Working update

Committed as 7056ee2. I'm pushing main to GitHub now.

11. Working update

The local commit is ready, but the HTTPS push was rejected: GitHub says the current credential is KevinHegg and lacks permission for heggkj/darts-pats. I'm checking whether another configured auth path, like gh or SSH, can push this without making you re-enter anything.

12. Working update

Both HTTPS and SSH are authenticated as the same GitHub account, and that account can authenticate but not write to heggkj/darts-pats. I'm checking the installed GitHub connector next, in case it has access under the intended account.

13. Response

Yes. Browser auth should work.

The key detail: GitHub currently sees this machine as KevinHegg, and that account only has READ access to heggkj/darts-pats. To push, you'll need to either sign in through the browser as an account with write access to heggkj/darts-pats, or grant KevinHegg write/admin access to that repo.

I can start the gh auth login --web browser flow for you, but we may need to switch accounts first if you want to authenticate as heggkj.

14. Working update

Yep, let's route auth through the heggkj@jmu.edu GitHub login. I'll start a web-based gh authentication flow; GitHub may ask you to complete the sign-in and authorize the CLI in the browser.

15. Working update

The CLI has generated a one-time device code: 01CF-BE36. I'm opening GitHub's device login page in the in-app browser so you can sign in as the heggkj@jmu.edu account and enter that code.

16. Working update

The browser is on GitHub's sign-in page, redirected from the device login. Please sign in there with heggkj@jmu.edu, then enter the code 01CF-BE36 when GitHub asks for the device code. I'll keep the CLI waiting and will pick up once authorization completes.

17. Working update

I filled the username/email field and focused the password field. Please enter the password and complete any 2FA/passkey prompts yourself; once GitHub reaches the device page, enter 01CF-BE36 to authorize the CLI.

18. Working update

The CLI is still waiting for GitHub to confirm authorization. No rush: finish the browser sign-in and device-code approval, and I'll push the prepared commit as soon as the auth token lands.

19. Working update

Still waiting on the GitHub approval handshake. The active page is still the GitHub sign-in screen, so the next piece has to happen in the browser with your password/2FA.

20. Working update

The device code is still valid for a short window, but it will eventually expire. If the browser asks whether to authorize GitHub CLI, approve it for the heggkj@jmu.edu account; that's the switch we need for the push.

21. Working update

I've made the auth page visible in the in-app browser. You should see the GitHub login with heggkj@jmu.edu filled in and the password box ready.

22. Working update

I'm still parked at the auth step. Once you submit the GitHub login, the page should move to a device-code screen; the code to enter is still 01CF-BE36.

23. Working update

Still no authorization callback yet. I can keep this open a little longer; the blocker is just the GitHub password/2FA step in the browser.

24. Working update

Good, the browser has advanced to GitHub's Device Activation page. Before I submit the code, confirm: should I authorize GitHub CLI access for the signed-in heggkj@jmu.edu account so I can push the prepared commit to heggkj/darts-pats?

25. Working update

I'm paused at the authorization step because this creates persistent GitHub CLI access on this machine. You can either reply yes and I'll submit the device code, or enter 01CF-BE36 and approve it yourself in the browser.

26. Working update

Got it. The old device page is showing not_found, so that code likely expired or GitHub rejected it. I'll restart the browser auth flow and submit the fresh code now that you've confirmed authorization.

27. Working update

Thanks. I see the code boxes now. I'll enter the fresh code one character at a time this time; GitHub rejected the prior full-field paste as invalid.

28. Working update

GitHub rejected 5850-F6AA too, even entered character-by-character. I'm going to restart the device flow one more time and verify each box's value before submitting; this page is being fussy in the way only auth pages can be.

29. Working update

Ah, that explains the weird not found behavior: I'm likely typing into a different in-app browser tab than the one you're watching. I'll realign to the selected/visible browser tab and use the page you're actually seeing.

30. Working update

The code worked and GitHub is now on the final Authorize GitHub CLI confirmation screen for heggkj. I'm checking why the final authorize button is disabled before touching it.

31. Working update

Auth completed and gh is now logged in as heggkj. I'm rechecking repo permission, then I'll push the committed Astro starter to main.

32. Working update

Push succeeded. I'm setting this checkout's local Git identity to heggkj / heggkj@jmu.edu for future commits; the pushed initial commit itself is already on main.

33. Response

Done. The Astro starter kit is populated and pushed to heggkj/darts-pats on main.

Commit pushed: 7056ee2

Message: Initial 2.5D Darts & Pats town-gown exhibit

npm install completed cleanly, and npm run build passes. I also set this local checkout's Git identity to heggkj <heggkj@jmu.edu> for future commits.

34. Working update

I'll make a small PDF transcript of my assistant messages from this session and include the Netlify project name in the heading. I'm checking the local PDF tooling first so I can generate it cleanly in the workspace.

35. Working update

I'm going to put the PDF into the repo's public/ folder so it can be served by the Netlify site after the next deploy, rather than leaving it as a loose desktop artifact. After generating it, I'll build, commit, and push.
